

ANNEX J TO  
CRITIQUE OF ALL NASA MARS WEATHER DATA, WITH EMPHASIS ON PRESSURE:  
Concessions by Ashima Research and How to Correctly Calculate Daylight Hours for MSL

This Annex was originally designed to correct disinformation about sunrise/sunset times at MSL. We used this pattern to raise a charge that all related Martian weather data is suspect. Ashima Research claimed to have derived its weather facts from the REMS Team, but sunrise/sunset times were never incorporated in the public reports that the REMS Team put out, so these mistakes would seem to belong to Ashima alone. It appears that Ashima essentially incorporated all our suggestion into their revised reports, although we suspect that a published report by them that the low temperature at MSL dropped from  $-75^{\circ}$  C on June 3, 2013 (Sol 293) to  $-114^{\circ}$  C on June 5, 2013 (Sol 295) is bogus. Temperatures were remarkably stable for the previous 292 sols, with lows from the minus mid 60s to the minus 70s.

### THE LONG SOUGHT ASHIMA RESEARCH CONCESSION POST.

From September 2012 through May 2013 we pointed out Ashima errors in conjunction with sunrise/sunset times and winds posted that made no sense. Finally they issued the following concession on May 10, 2013:

#### Weather app update

Posted on May 10, 2013 by Chris

For the first 268 sols of data collected by REMS we've archived the XML data files published by CAB without any modifications. We also collected these files into a *REMS\_climate* file that powers our mobile HTML5 app.

Annex J to Critique of All NASA Mars Weather Data Calculations for daylight for MSL at  $4.59^{\circ}$  South

We've known about a few small flaws in the data stream for a while, including the lack of wind data, occasional copy-paste errors and changes in the language used for terrestrial dates (the files are manually updated). However, this is not the 'science' data (which can be found on NASA's Planetary Data System) and this site is not maintained by/for the REMS science team. So, while we can guess at corrections to the data, we don't add or create data without a very good reason.

Last month, spaceappschallange launched a project called "Wish You Were Here" to provide an "interesting representation of weather on Mars" using the REMS public feed. This led to most (if not all) of the participating groups to base their projects on our archived data feed and blame us for the errors they found. A few even tried to correct the data and added in new and interesting errors while doing so.

We can't fix all of the data, but the data we release now contains a few extra values related to time on Mars that we calculate using our Python tools that we also use in our Data Assimilation project. The new data does not replace the old data, which still exists in the files, but we've added some fields to provide our best estimates of the timing data. Some of the projects formed in the spaceappschallange have archived our dataset, so it might take them a while to update, but the data is live in our weather app right now!

In detail, we have:

David A. Roffman & Barry S. Roffman

**1. Calculated the sunrise and sunset times at MSL in Mean and True Solar Times. These values are much better than the fixed values provided by the original data, but still rely on some assumptions.** We assume that the mission Sol in question is referenced correctly in the original data and calculate the Mars Solar Date and J2000 ephemeris offset using this data. Once this date is found we (mathematically) look for the sunrise and sunset, noting the times it happens. Times are now given in a 24 hour clock format.

2. Calculated the Heliocentric Longitude, L<sub>s</sub>. These calculated values rely on the same assumption about Sol number as the sunrise/sunset calculation. It turns out the original data is pretty close to our calculated values so we think the original data is correct. The difference between the two is in the origin of those values used to calculate L<sub>s</sub>. Our L<sub>s</sub> comes directly from the Sol number. The original CAB L<sub>s</sub> may have a better source for this value in the raw data, or they may start from the “posted” Earth date.

### **3. Removed the wind speed and direction data.**

4. Normalized the ‘posted’ or ‘terrestrial date’ to an ISO standard format. In our weather app (that has been running since MSL landed!) we present the date in a format determined by your Locale settings.

(As a reminder, neither the original nor calculated data provided by the app should be relied on for mission planning, weather forecasting, or conspiracy theories. NASA provides many free tools to find the time on Mars with *extremely good accuracy* if you need it.)

Exact times of sunrise and sunset are important in discussions relating the frequent inverse relationship seen between temperature and pressure for Viking 1, Viking2, and MSL – all of which employed radio thermoelectric generators. The affects of these heaters and other cyclic heat sources on pressure transducers are of prime interest.

Ashima took the liberty of altering the REMS reports of September 1 to September 5, which had shown the pressure to be between 742 and 747 hPa (Mbar), pressure often equal to that of Vail, Colorado.

Our taxpayers paid ~\$2,500,000,000 for the MSL lander. Earlier I wrote that for that “we received a set of data that is easy to refute. Ashima and the REMS Team owe the public an apology, and an admission that corrections noted in this report are true.” The retraction on their part was a good start, but the real issue remains pressure. If pressures shown by the REMS Team for September 1 to 5, 2013 turn out to be true, then Mars is much more like the Earth than we have been led to believe.

## MARTIAN DAYLIGHT CALCULATIONS BY DAVID A. ROFFMAN

The first step is to specify the latitude,  $\varphi$ . For purposes of this calculation, the latitude used was the actual latitude of the MSL on Mars, namely  $4.59^\circ$  South (written as  $-4.59$ ). Next the declination ( $\delta$ ) must be calculated:

$$\delta = \arcsin((\sin(25.19) * \sin(\lambda_{\text{sun}}))).$$

The required input is the  $L_s$ , which is  $\lambda_{\text{sun}}$ . The hour angle is then  
 $H = \arccos((\text{SIN}(-.17) - \text{SIN}(\varphi) * \text{SIN}(\delta)) / (\text{COS}(\varphi) * \text{COS}(\delta))).$

This output must be in degrees. A reference speaks of calculating the solar transit (local noon). However, it also notes that the sunrise and sunset times are the local noon time  $-/+ 1.027491^*H/360$ . By taking the equations for sunrise and sunset times (the actual formulae for the Julian dates are irrelevant as they share a common term that will be canceled) and subtracting the sunrise from the sunset one, a number is obtained. This is the time interval between the sunset and sunrise times, and is hence the length of day. The length of day is:  $2*1.027491^*H/360$ . Multiply by 24 to get hours. The table that follows indicates what the total hours and minutes are for each  $L_s$  (solar longitude). The  $L_s$  can be related to a specific date via the on-line calculator at [http://www-mars.lmd.jussieu.fr/mars/time/martian\\_time.html](http://www-mars.lmd.jussieu.fr/mars/time/martian_time.html). The tables give only the numbers of hours and minutes of daylight. Or a sol with 12 hours 10 minutes of daylight, half that time is before local noon and half the time is after local noon, so such a day would have sunrise at 5:55 and sunset at 18:05. The actual time may vary slightly as a result of local topography. For example, MSL is headed for Mount Sharp which rises ~5 km from the valley floor, although the top of the mountain is only about 838 m above MOLA areoid ([http://wray.eas.gatech.edu/Wray2012\\_GaleReview-acceptedIJA.pdf](http://wray.eas.gatech.edu/Wray2012_GaleReview-acceptedIJA.pdf)). Ashima Research rounds off its sunrise *and* sunset times to the nearest minute, so this fact alone can contribute up to a minute of difference between our calculations and any figures they publish. It appears that their new set of figures is almost always within one or two minutes of our calculation, is based on Mars being a perfect sphere (another small source of error).

**Understanding where Mars is in its orbit.** The solar longitude  $L_s$  is the Mars-Sun angle, measured from the Northern Hemisphere spring equinox where  $L_s=0$ .  $L_s=90$  thus corresponds to summer solstice, just as  $L_s=180$  marks the autumn equinox and  $L_s=270$  the winter solstice (all relative to the northern hemisphere). In trying to understand where Mars is in its orbit, it's important to know that while all Martian months involve a change of 30 degrees, there is a large variation in number of days in each of the 12 months there, and also a large variation in angular speed around the sun (see Figure 1 and Table 1 below). In working up estimates for the length of any given day I used Table 2. This allowed me to project within a day or 2 over the Martian year where the planet would be, so that I could compare the length of day on Mars with a similar position in Earth's orbit. Small errors were introduced where the daily rate of change in  $L_s$  was not quite the monthly average shown in the last column of Table 2, especially around perihelion.

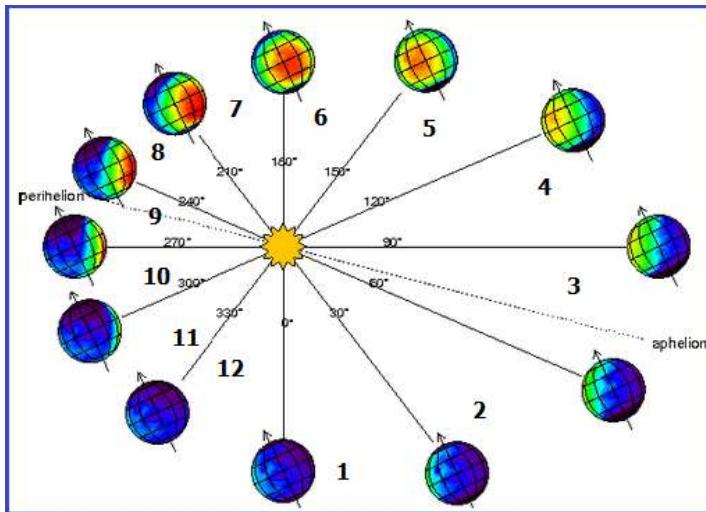

Figure 1 above – Position of Mars at the start of each of its 12 months. Perihelion occurs between month 8 and 9, aphelion in between month 2 and 3. As per table 2 below, Mars experience its greatest  $\Delta Ls$  in degrees per day around perihelion.

MARS MONTH/	END SOL	START SOL	DAYS	Degrees per month	$\Delta Ls$ Degrees per Day
